

Find Smallest Value in an Array - TCS Style

Goal: Read an array from input and print the smallest number.

1. Python Code

```
# Problem: Find the smallest value in an array
# Type: TCS NQT Coding Practice
```

```
n = int(input())
arr = list(map(int, input().split()))
```

```
smallest = arr[0]
```

```
for num in arr:
    if num < smallest:
        smallest = num
```

```
print(smallest)
```

2. Input and Output

Input:

```
5
2 3 6 54 1
```

Output:

```
1
```

3. Simple Explanation

Step	Meaning
1	<code>n = int(input())</code> reads how many elements are present in the array.
2	<code>arr = list(map(int, input().split()))</code> reads all numbers and stores them in a list.
3	<code>smallest = arr[0]</code> assumes the first element is the smallest value.
4	The for loop checks each number one by one.
5	If the current number is smaller than <code>smallest</code> , we update <code>smallest</code> .
6	After the loop ends, <code>print(smallest)</code> prints the final smallest value.

4. Dry Run

For array [2, 3, 6, 54, 1], first `smallest` = 2. Then the loop compares each value. Finally, 1 is smaller than 2, so `smallest` becomes 1. The answer is 1.

Tip: In online coding tests, do not write input messages like "Enter number". Use only `input()` and print the final answer.
